Potential of MWA for spectral line observations

Slava Kitaeff, Andrew Walsh

Curtin University

THE UNIVERSITY OF
WESTERN AUSTRALIA

Science (likely incomplete)

- High redshift HI sources
- Radio Recombination Lines
 - Diffused warm gas (CII)
 - HII envelops
- Molecular lines and masers

Radio Recombination Lines

Rydberg atoms, or atoms with a single electron at a high quantum number, occur in interstellar medium.

As the electron cascades to lower energy levels, each transition creates a radio recombination line, or RRL.

At frequencies above 100 MHz these lines appear in emission.

At frequencies below 100 MHz, the excitation temperature of the atoms approaches the typical gas kinetic temperature and the lines appear in absorption.

Low Frequency Galactic RRLs

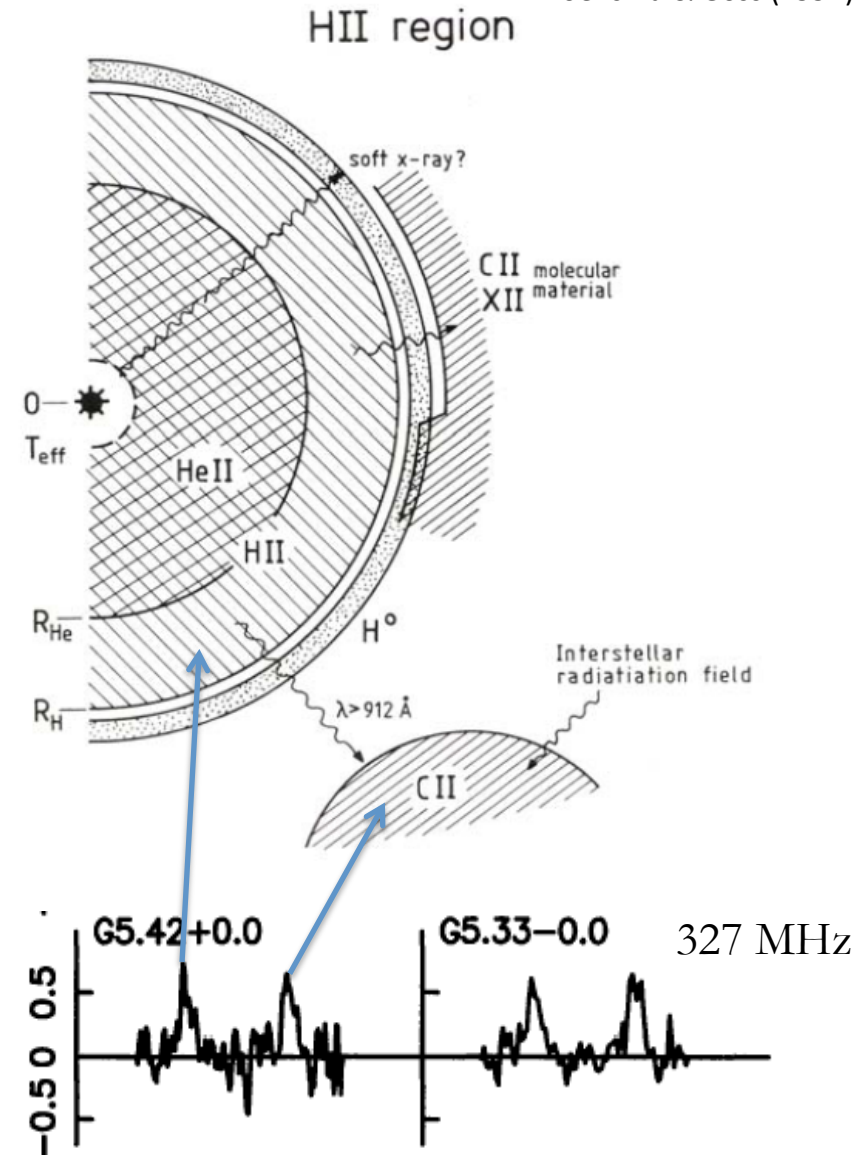

Roelfsma & Goss (1992)

HII regions

- $N_e \sim 1-10 \text{ cm}^{-3}$
- $T_e \sim 7000\text{K}$
- Observed down to 327MHz

Atomic clouds

- $N_e \sim 0.1 \text{ cm}^{-3}$
- $T_e \sim 25 \div 100\text{K}$
- Photodissociation regions - not enough UV to ionize HI
- Diffuse emission
- Observed down to 25 MHz

RRLs - EoR Contaminant

The line spacing for the α lines is $\Delta\nu \sim 3\nu/n$ ($\sim 1\text{MHz}$ @ 150MHz and $\sim 150\text{kHz}$ @ 50kHz), and other transitions are also going to be present.

Pritchard & Loeb, 2010
Nature 469 772

(Stepkin et al. 2007
MNRAS 374, 852)

How bad?

The magnitude of the spectral fluctuations expected from the HI signals for the dark ages, first stars and epoch of reionisation is roughly in the range 10^{-4} to 10^{-5} .

The magnitude of the spectral fluctuations from RRLs would be of order 10^{-3} to 10^{-4} .

If there is RRL-hosting gas at high Galactic latitudes, the spectral fluctuations arising from RRLs could be comparable to or exceed those from the desired HI signals.

What we know so far

CRRLs in the plane are seen from $-20 < l < 20$, but only on isolated sightlines elsewhere.

Why to study CRRs?

At large n (>300 for MWA band), the atoms are very big and fragile. Variations in pressure, temperature and density as well as radiation broadening affect the line profile. This makes these lines a sensitive probe for ISM.

Warm gas is thought to be the major component of Galactic gas, however, the distribution in the larger Galaxy is very poorly known.

When RRLs at multiple frequencies are combined with information from HI, molecular, and CII observations, a comprehensive picture of the absorbing clouds in Galaxy can be built.

Frequencies and resolution

Line width $\sim 50\text{-}70\text{ km/s}$

CRRL - 10KHz is OK

requires at least 3KHz frequency resolution

Expanding to 50MHz would be great!

CRRL from extragalactic sources (M82)

LBA measurements (30-78 MHz)

Morabito et al. (in prep):

First detection of CRRLs from an extragalactic source

(32channels/subband, stacking 22 subbands)

M. C. Toribio

LOFAR Status Meeting, ASTRON
August 20th, 2014

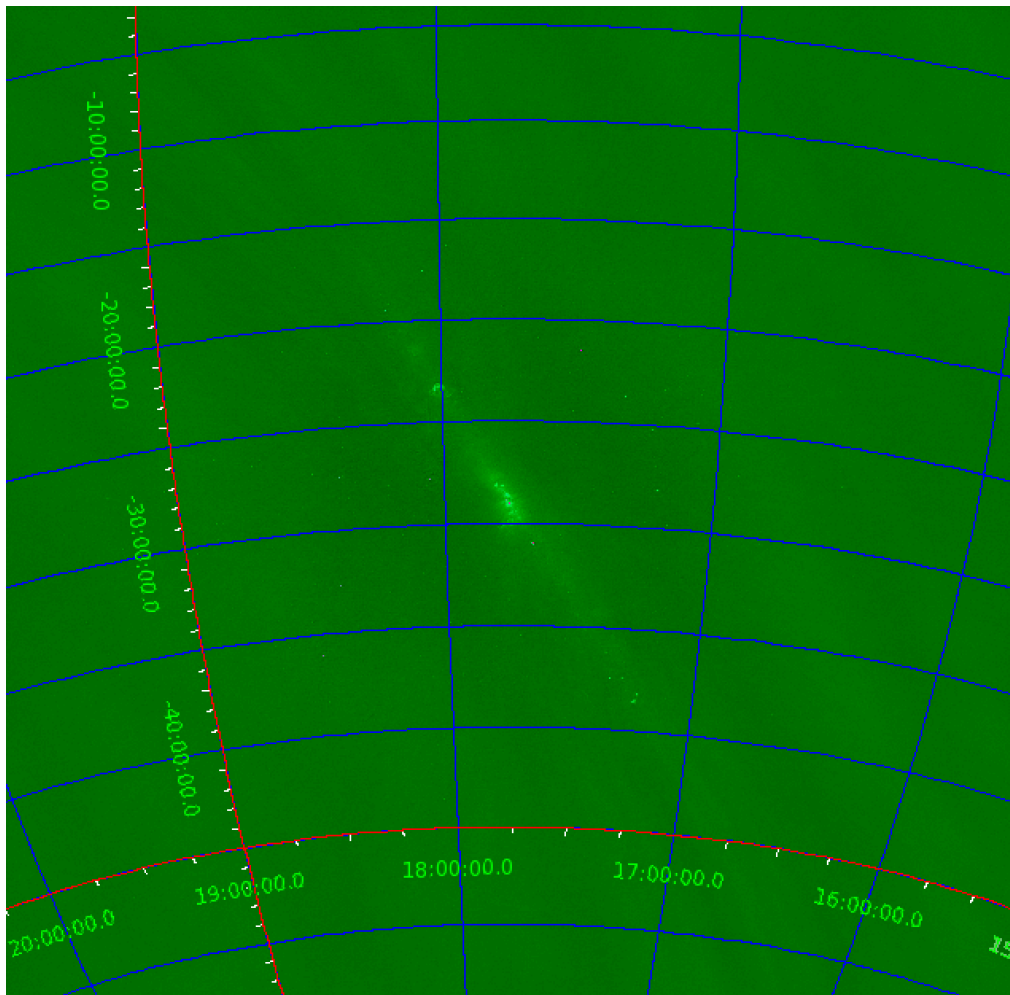

Why to study HRRRLs?

- Envelops of normal HII areas
- Interacting HII bubbles in star formation regions (requires better than 10KHz frequency resolution)

MWA: RRLs towards the Galactic Centre

C537 α + C538 + C539 α (Smirnov & Kitaeff, 1996)

C443 α + C447 α (Anantharamaiah et al., 1988)

Detectability with 128T

Surface brightness is critical

$$\Delta t_{\text{int}} = \left(\frac{m}{f \times DF} \frac{T_{\text{sys}}}{\Delta T} \right)^2 \frac{1}{N_{\text{pol}} N_{\text{lines}} \Delta \nu}$$

5 σ detection, of 10⁻³ optical depth lines

128T

- 32 tiles within 100m radius – 13 hours per line
- 50 tiles within 250m radius – 250 hours per line
- Stacking- 27 lines in band

Impact of PFB channelization

Cn α line	Freq (MHz)	Coarse Channel	Channel
338	169.6333	x	x
339	168.1435	131	2925
340	166.6664	130	2777

358	142.8012	112	391
359	141.6128	111	272
360	140.4376	110	154
361	139.2754	109	39
362	138.1259	108	x
363	136.9891	107	x
364	135.8647	x	x

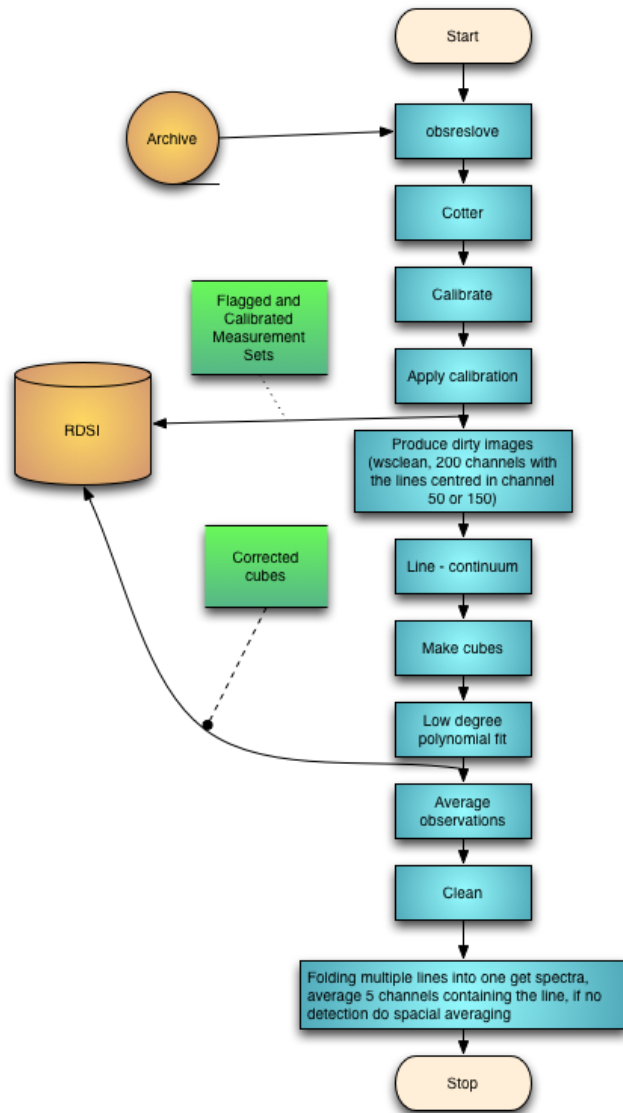

- 27 lines in total
- 10 can not be used (37% of data)
- One “fat” band would be great!

Required integration time with MWA-X

- With 100 tiles within 250m radius, and all 27 lines the integration time ~2 hours
- MWA-X would make RRL survey possible

Data reduction

- 1700 channels to image - computationally expensive
- About 1 hour of data has been imaged
- Some strategies for averaging, stacking and continuum subtraction are developed but not fully tested.

Molecular line emission with the MWA

- In addition to radio recombination lines, there are a number of spectral lines from molecules that are expected to be easily detectable. These include:
- SH, H₂CO, HNCO, CH₂NH, H₂S, H₂CS (and many more, like OH at 55MHz, if the band is expanded)
- The ratio of these simple molecules can tell us about the basic physical conditions in the ISM (density, temperature, ionisation rate etc.)

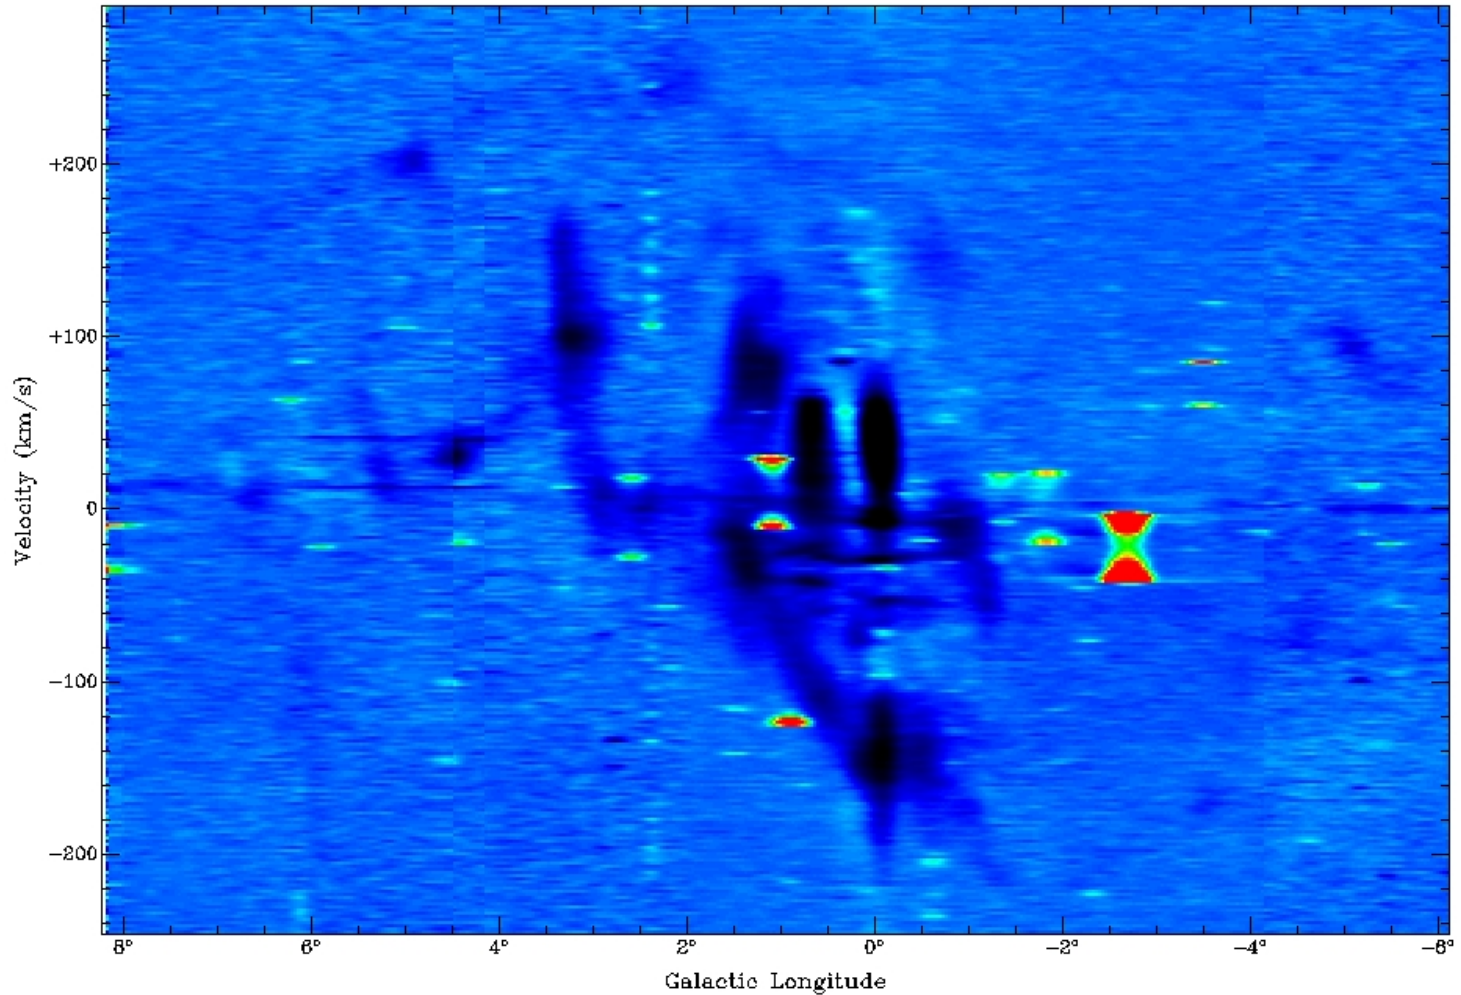

SH – the mercapto radical

- Four spectral lines at 100.29, 111.48, 111.55, 122.37MHz
- Equivalent to the four OH ground-state line at 1612, 1665, 1667 and 1720MHz
- OH lines are widespread and seen as masers, thermal emission and absorption
- SH likely to be 1/25 the abundance of OH, so SH can fill in places where OH is optically thick
- If the band is expanded to 50MHz, it would enable simultaneous observations of OH and SH

OH in the Centre of the Galaxy from SPLASH

Summary

- MWA should be able to detect both HRRL and CRRL
- Mapping CRRL is important for EoR
- Extragalactic RRLs might be possible to observe with MWA-X
- Molecular lines can be observed
- Wishes for MWA-X
 - More tiles in the central area
 - Better frequency resolution (ideally 1KHz)
 - Better spatial resolution
 - One “fat” band
