

<b>Title:</b>	The Crab Pulsar at Centimeter Wavelengths II: Single Pulses
<b>arXiv:</b>	arXiv:1608.08881
<b>Figure:</b>	<p>The figure consists of two vertically stacked panels sharing a common x-axis labeled 'Time (Microseconds)' ranging from 0 to 6. The top panel is a line plot showing 'Intensity (Jy)' on the y-axis, ranging from 0 to 200. It displays a single, sharp pulse that rises from a baseline of about 20 Jy at 1.5 microseconds to a peak of approximately 200 Jy at 2.2 microseconds, before decaying back to the baseline by 4 microseconds. The bottom panel is a dynamic spectrum showing 'Intensity (kJy)' on a color scale from 0 to 2 on the right, plotted against 'Time (Microseconds)' on the x-axis and 'Frequency (GHz)' on the y-axis, ranging from 42 to 44. The dynamic spectrum shows a dispersive tail of the pulse, with the highest intensity (red/yellow) concentrated between 2 and 4 microseconds and 42.5 and 44 GHz. A color bar on the right indicates intensity levels from 0 to 2 kJy.</p>
<b>Caption:</b>	<p>The total intensity of a Main Pulse recorded at 43.25 GHz and de-dispersed using DM of 56.794 pc-cm<sup>-3</sup> (taken from Jodrell Bank monitoring for our observing date) is shown with a time resolution of 44.8 ns. The frequency resolution of the dynamic spectrum is 78 MHz. The Intensity contour levels in the dynamic spectrum are 0.2, 0.5, 1, and 2 kJy. The off-pulse noise level for the total intensity is 15.2 Jy, and for the dynamic spectrum, 110 Jy</p>

<b>Title:</b>	Towards optimal extraction of cosmological information from nonlinear data

<b>Title:</b>	Merging Galaxies with Tidal Tails in COSMOS to $z=1$
<b>arXiv:</b>	arXiv:1608.04298
<b>Figure:</b>	<p>The figure consists of four panels arranged in a 2x2 grid, showing the color-color diagram <math>U-V</math> versus <math>V-J</math> for merging galaxies with long tidal tails. The panels correspond to different redshift bins: <math>0.2 \leq z &lt; 0.4</math> (top-left), <math>0.4 \leq z &lt; 0.6</math> (top-right), <math>0.6 \leq z &lt; 0.8</math> (bottom-left), and <math>0.8 \leq z &lt; 1</math> (bottom-right). Each panel displays a large cloud of gray points representing the parent sample of 35,076 galaxies. Overlaid on these are black circles representing galaxies with tidal dwarf galaxy (TDG) candidates and green circles representing galaxies with long tails. Solid lines in each panel indicate the adopted division between quiescent galaxies (above the line) and star-forming galaxies (below the line). A legend in the top-right panel identifies the symbols: black circles for 'gal. with TDG' and green circles for 'gal. with long tail'.</p>
<b>Caption:</b>	<p>The <math>U - V</math> Vs. <math>V - J</math> diagram of 461 merging galaxies with long tidal tails (solid circles) in comparison with the parent sample of 35 076 galaxies (gray points). The black (green) circles represent mergers containing (or not) tidal dwarf galaxy candidates. The solid lines show the adopted division between the star-forming and quiescent galaxies in each redshift bin.</p>

<b>Title:</b>	Interacting galaxies: co-rotating and counter-rotating systems with tidal tails
<b>arXiv:</b>	arXiv:1312.0560
<b>Figure:</b>	<p>The figure consists of six histograms arranged in a 3x2 grid. The left column is labeled 'Galaxies' and the right column is labeled 'AGN'. The top row shows the distribution of redshift (<math>z</math>), the middle row shows the distribution of absolute r-band magnitude (<math>\log(M_r)</math>), and the bottom row shows the distribution of stellar mass (<math>M_r</math>). Each plot compares co-rotating pairs (solid blue lines) and counter-rotating pairs (dotted red lines). The y-axis for all plots is the fraction <math>f</math>.</p> <ul style="list-style-type: none"> <li><b>Top-left (Galaxies, <math>z</math>):</b> The x-axis ranges from 0 to 0.1. The y-axis ranges from 0 to 0.3. Co-rotating pairs peak at <math>z \approx 0.06</math>, while counter-rotating pairs peak at <math>z \approx 0.04</math>.</li> <li><b>Top-right (AGN, <math>z</math>):</b> The x-axis ranges from 0 to 0.1. The y-axis ranges from 0 to 0.3. Both samples peak at <math>z \approx 0.08</math>.</li> <li><b>Middle-left (Galaxies, <math>\log(M_r)</math>):</b> The x-axis ranges from 9 to 11. The y-axis ranges from 0 to 0.2. Co-rotating pairs peak at <math>\log(M_r) \approx 10.2</math>, while counter-rotating pairs peak at <math>\log(M_r) \approx 10.1</math>.</li> <li><b>Middle-right (AGN, <math>\log(M_r)</math>):</b> The x-axis ranges from 9.5 to 11.5. The y-axis ranges from 0 to 0.4. Both samples peak at <math>\log(M_r) \approx 10.8</math>.</li> <li><b>Bottom-left (Galaxies, <math>M_r</math>):</b> The x-axis ranges from -18 to -23. The y-axis ranges from 0 to 0.25. Co-rotating pairs peak at <math>M_r \approx -20.2</math>, while counter-rotating pairs peak at <math>M_r \approx -20.1</math>.</li> <li><b>Bottom-right (AGN, <math>M_r</math>):</b> The x-axis ranges from -19 to -23. The y-axis ranges from 0 to 0.3. Both samples peak at <math>M_r \approx -20.8</math>.</li> </ul>
<b>Caption:</b>	<p>Distribution of redshift (top), absolute r-band magnitude (middle) and stellar mass content (bottom) for the non-AGN galaxy sample (left) and for the AGN galaxy sample (right) in co and counter-rotating pairs. The solid lines correspond to the co-rotating and the dotted lines correspond to the counter rotating galaxy pairs, respectively.</p>

<b>Title:</b>	OMEGA - OSIRIS Mapping of Emission-line Galaxies in A901/2: III. - Galaxy Properties Across Projected Phase Space in A901/2
<b>arXiv:</b>	arXiv:1706.05199
<b>Figure:</b>	<p>The figure consists of three panels. The left panel is a histogram showing the distribution of the difference between prism and spectroscopic redshifts, <math>z_{\text{prism}} - z_{2\text{dF,VIMOS}}</math>. The x-axis ranges from -0.04 to 0.02, and the y-axis (Number) ranges from 0 to 60. A text box indicates a median offset of -0.004. The middle panel is a scatter plot of <math>z_{2\text{dF,VIMOS}}</math> versus <math>z_{\text{prism}}</math> for <math>z_{\text{prism}} \geq 0.12</math> (N=143). It shows a positive correlation with a solid black line representing <math>y = x</math> and a dashed red line representing a linear fit <math>y = 0.65x + 0.06</math>. The right panel is a scatter plot of <math>z_{2\text{dF,VIMOS}}</math> versus <math>z_{\text{prism,corrected}}</math>, labeled 'Post correction', showing a much tighter correlation with the <math>y = x</math> line.</p>
<b>Caption:</b>	<p>This figure compares the spectroscopic and prism redshifts for a subset of 143 galaxies having both kinds of redshifts. The left panel shows the distribution of offsets between the spectroscopic and prism redshifts. The middle panel shows that the offset is redshift dependent. The solid line is <math>y = x</math>. The dashed line is a fit to the data. In the right panel, we have used the fit from the middle panel to recalibrate the prism redshifts to better match the spectroscopic redshifts.</p>

<b>Title:</b>	OMEGA - OSIRIS Mapping of Emission-line Galaxies in A901/2: III. - Galaxy Properties Across Projected Phase Space in A901/2
<b>arXiv:</b>	arXiv:1706.05199
<b>Figure:</b>	<p>The figure is a scatter plot showing the spatial distribution of galaxies in the A901/2 field. The x-axis represents Right Ascension (RA) in degrees, ranging from 148.80 to 149.40. The y-axis represents Declination (DEC) in degrees, ranging from -9.7 to -10.3. The plot contains data points from four different redshift sources: Vimos/AAT (blue diamonds, N=359), OMEGA (green squares, N=273), Prism (red circles, N=224), and four subclusters (black triangles). The subclusters are labeled A901a (top-left), A901b (top-right), A902 (bottom-left), and SW Group (bottom-right). Each subcluster is enclosed by a circle representing its sphere of influence (R200). The plot shows a clear separation between the subclusters and the main galaxy population.</p>
<b>Caption:</b>	The top panel shows the spatial distribution of the 856 galaxies in sample S2 coded by the source of the adopted redshifts. The four subclusters are separately labelled, and their spheres of influence (R200) are shown as circles.

<b>Title:</b>	Interstellar extinction curve variations towards the inner Milky Way: a challenge to observational cosmology
<b>arXiv:</b>	arXiv:1510.01321
<b>Figure:</b>	
<b>Caption:</b>	Subset of OGLE-III subfields shown in red overlaid on an optical image of the Galactic bulge with Galactic coordinate system shown as well. The subfields used in this work, for which we also use the matching V V V photometry, are shown in green.

<b>Title:</b>	Ages of Type Ia supernovae over cosmic time
<b>arXiv:</b>	arXiv:1409.2951
<b>Figure:</b>	<p>The figure consists of three heatmaps arranged horizontally, each with 'Galaxy Stellar Mass' on the x-axis (ranging from 8 to 12) and 'Stellar Age' on the y-axis (ranging from 0 to 12).    - The left plot, titled 'Normalized Galaxy SFHs', shows a broad distribution of stellar ages across the mass range, with higher density at lower ages and lower masses.    - The middle plot, titled 'SN Ia Age Distributions', shows a similar broad distribution but with a distinct concentration of points at low stellar ages across all masses.    - The right plot, titled 'Final SN Ia Number Density', shows a very sharp concentration of points at low stellar ages, primarily between masses 10 and 12, indicating that Type Ia supernovae are predominantly produced in older, more massive galaxies.</p>
<b>Caption:</b>	<p>Left: Normalized mean galaxy SFHs as a function of total stellar mass. Middle: SN Ia age distribution versus host galaxy mass (not re-normalized: age distribution per unit mass). Right: Intrinsic distribution of SNe Ia in progenitor age-host mass space in the local Universe (<math>z = 0</math>).</p>

<b>Title:</b>	Linking the structural properties of galaxies and their star formation histories with STAGES
<b>arXiv:</b>	arXiv:1510.01115
<b>Figure:</b>	<p>The figure consists of four panels, each representing a different galaxy morphology: E (top-left), S0 (top-right), Sp (bottom-left), and Irr (bottom-right). Each panel contains a scatter plot of <math>\log(\text{SSFR yr}^{-1})</math> on the y-axis (ranging from -12 to -9) versus <math>\Delta(W_{462} - W_{518})</math> on the x-axis (ranging from -1.0 to 0.5). The scatter plots use different symbols to represent galaxy types: black squares for relaxed systems, blue circles for disturbed galaxies not classified as mergers, and red symbols for visual mergers. Plus signs represent objects with only SFR upper or lower limits. Below each scatter plot are two histograms: the top one shows the distribution of <math>\log(\text{SSFR yr}^{-1})</math> (y-axis: 0.0 to 1.2) and the bottom one shows the distribution of <math>\Delta(W_{462} - W_{518})</math> (y-axis: 0.0 to 1.2). The histograms are normalized to a maximum value of one. Three data series are shown in each histogram: relaxed galaxies (black dashed line), disturbed galaxies (blue solid line), and visual mergers (red histogram).</p>
<b>Caption:</b>	<p>Specific SFR vs. <math>\Delta(W_{462} - W_{518})</math> for cluster galaxies of all morphologies. As in Fig. 2, black squares correspond to relaxed systems, blue circles to disturbed galaxies not classified as mergers and red symbols to visual mergers. Objects with only SFR upper or lower limits are presented as pluses with appropriate colours. In the accompanying histograms, the black dashed line shows the relaxed galaxies, the blue solid line the disturbed ones, and the red histogram the visual mergers. The SSFR histogram excludes objects with only SFR upper or lower limits. The <math>\Delta(W_{462} - W_{518})</math> histogram includes all objects. In all cases, the histograms are normalized to a maximum value of one in order to amplify the differences between the distribution functions.</p>
